

Porfolio One : Expressions

Program: Current Exchange (USD TO PHP)

Converting USD TO PHP allows comparison of goods and cost of services in different country. This can be use for travelling, business trading, and investments for me and others.

```
In [45]: # Get the amount in USD
        usd_amount = input("Enter amount in USD: $")
        usd_amount = float(usd_amount)

        # Find the exchange rate
        exchange_rate = input("Enter exchange_rate in PHP: PHP")
        exchange_rate = float(exchange_rate)

        # all done
        converted_amount = usd_amount * exchange_rate
        print("Converted_amount: PHP", converted_amount)
```

Converted_amount: PHP 50.0528

Market Price

The purpose of this is to get the accurate total price for buyer. This also helps manage inflation, which is big help for seller and buyer.

```
In [46]: # Identity the price and weight of pork
        price = input("Enter price per kilogram: PHP")
        price = float(price)
        weight = input("Enter weight in kilogram: ")
        weight = float(weight)

        # Calculate the total price
        total_price = price * weight

        # all done
        print("Total_price: PHP", total_price)
```

Total_price: PHP 875.0

General Weighted Average

This code is used for evaluating the student's academic performance, to determine the elligibility for scholarships, and basis for honors.

```
In [44]: # Get the grade for each subjects
        calculus = input("Enter calculus grade: ")
        calculus = float(calculus)
        anachem = input("Enter anachem grade: ")
        anachem = float(anachem)
        anachemlab = input("Enter anachemlab grade: ")
        anachemlab = float(anachemlab)
        comprog = input("Enter comprog grade: ")
        comprog = float(comprog)
        physics = input("Enter physics grade: ")
        physics = float(physics)
        physicslab = input("Enter physicslab grade: ")
        physicslab = float(physicslab)
        pathfit = input("Enter pathfit grade: ")
        pathfit = float(pathfit)
        artapp = input("Enter artapp grade: ")
        artapp = float(artapp)
        entrep = input("Enter entrep grade: ")
        entrep = float(entrep)

        # Calculation of Averafe
        average = (calculus + anachem + anachemlab + comprog + physics + physicslab + pathfit + artapp + entrep) / 9
```

```
# all done
print("Your average grade is: ", average)
```

Your average grade is: 2.066666666666667
